ECOLOGY AND CONSERVATION STATUS OF TUCUXI (*Sotalia fluviatilis*) IN THE PACAYA-SAMIRIA RESERVE, PERU

TAMARA L. MC GUIRE^{1,2,*}

ABSTRACT: The distribution, relative abundance, group size, reproductive seasonality, and conservation status of tucuxi (*Sotalia fluviatilis*) were investigated in Peru's Pacaya-Samiria National Reserve from 1996 to 2000. Data collection consisted of boat-based surveys of dolphins and habitat, necropsies, photo-identification of individual dolphins, and interviews with local people. Mean encounter rates were between 0.01-0.80 tucuxi/km in rivers, and 0.05-2.17 tucuxi/km² in lakes, and were within the ranges reported for riverine tucuxi throughout their distribution. Encounter rates were highest in confluences, intermediate in lakes, and lowest in rivers. Encounter rates increased with river width. Most tucuxis were seen within 100m from shore in large rivers, and large groups were associated with confluence areas and mid-channel islands. Within lakes, tucuxis were associated with areas of deeper water. Tucuxis were not found in waters <3m depth in rivers, or <1.8m depth in lakes. Seasonal differences in encounter rates did not exist in lakes and rivers. In confluences tucuxis occurred in highest densities during low water, and lowest densities during high water. Diurnal patterns of occurrence were not observed. Tucuxis were seen most often as singles or pairs, although groups as large as 13 were observed. Significant seasonal differences in group size were not detected. Neonate tucuxi were observed in all seasons, with a slight peak in encounter rates during high water. Abundance estimates were affected by survey methods, and strengths and weaknesses of various methods are discussed. Photo-identification rates were low, and this method did not yield information about tucuxi site fidelity, movement patterns, social structure, or population size. Local people in the Reserve did not seem to have the same myths and general apprehension about tucuxis as for the other sympatric dolphin, *Inia*. There was no evidence that tucuxi were poisoned by fishermen, unlike *Inia*. Potential threats to tucuxi in this region were entanglement in fishing gear, mercury in migratory fish from gold mining elsewhere, oil spills, ship strikes, and disturbance from boats. Only one dead tucuxi was encountered, and had been entangled in a turtle net. Tucuxi teeth were found for sale in local markets.

RESUMEN: Desde 1996 al año 2000 se estudió la distribución, abundancia relativa, tamaño de grupo, estacionalidad reproductiva y el estatus del delfín de río tucuxi (*Sotalia fluviatilis*) en la Reserva Nacional Pacaya-Samiria del Perú. La toma de datos consistió en evaluaciones de delfines y hábitat desde botes, necropsias, foto-identificación de individuos, y entrevistas con gente local. Las tasas medias de encuentro se encuentran entre 0.01-0.80 tucuxi/km en ríos, y de 0.05-2.17 tucuxi/km² en lagos, y estuvieron dentro de los rangos reportados para tucuxi a lo largo de su distribución. Las tasas de encuentro fueron más altas en confluencias, intermedias en lagos y las más bajas en ríos. Las tasas de encuentro incrementaron con el ancho del río. La mayoría de los delfines fueron vistos a 100m de la orilla de ríos principales, y grupos numerosos fueron asociados con confluencias y canales al medio de islas. En los lagos, tucuxis estuvieron asociados con áreas de aguas mas profundas. En ríos, tucuxis no fueron encontrados en aguas <3m de profundidad, o <1.8m profundidad en lagos. No se encontraron diferencias estacionales en las tasas de encuentros en lagos y ríos. Tucuxis se encontraron en mayores densidades en confluencias durante aguas bajas y en bajas densidades durante aguas altas. No se observaron patrones de ocurrencia diurna. Se observaron más a menudo tucuxis solitarios o en pares, aunque se observaron grupos de hasta 13. No se detectaron diferencias estacionales significativas. En todas las estaciones se observaron neonatos de tucuxi con un ligero pico durante aguas altas. Las estimaciones de abundancia fueron afectadas por los métodos de muestreo, y se discute la fortaleza y debilidad de varios métodos. Las tasas de delfines foto-identificados fueron bajas y no permiten información relacionada con fidelidad de lugar, patrones de movimiento, estructura social, o tamaño poblacional. La gente local de la reserva no tiene los mismos mitos y aprensiones generales sobre los tucuxis como para el simpátrico delfín, *Inia*. No se encontró evidencia que los pescadores envenenaran a *Sotalia* como con *Inia*. Las potenciales amenazas al tucuxi en esta región fueron el emmallamiento en redes de pesca, mercurio presente en peces migratorios vertidos por minas de otras regiones, derrames de petróleo, tráfico y colisiones con embarcaciones. Solamente se encontró un tucuxi muerto que había sido enredado en una red para tortugas. Se encontraron dientes de tucuxi en mercados locales.

KEYWORDS: *Sotalia fluviatilis*, tucuxi, river dolphin, Pacaya-Samiria Reserve, Peruvian Amazon, abundance estimates, seasonality.

Introduction

The conservation status of the tucuxi (*Sotalia fluviatilis*) is designated as 'data deficient' by the IUCN Red List³. Population estimates of tucuxi are scarce, in part because of the vast range of the species (the Amazon Basin and the lower Orinoco River Basin), and in part because of challenging logistics and survey methods. Most studies

have reported results in terms of relative dolphin densities or encounter rates (Layne, 1958; Magnusson *et al.*, 1980; Best and da Silva, 1989; Borobia *et al.*, 1991; da Silva, 1994; da Silva and Best, 1996; Herman *et al.*, 1996; Leatherwood, 1996; Trujillo, 1992; Vidal *et al.*, 1997; Galindo, 1998; Henningsen, 1998; Reeves *et al.*, 1999; McGuire, 2002; Martin *et al.*, 2004), as true densities are often difficult to obtain due to the complex

habitat, elusive behavior, and patchy distribution of tucuxi. Several related studies of river dolphin (*Sotalia* and *Inia*) ecology and conservation have been conducted in Peru's Pacaya-Samiria Reserve as part of a long-term project initiated in 1991 (Leatherwood, 1996; Leatherwood *et al.*, 2000), and continued by Henningsen (1998), Zúñiga (1999), and McGuire (2002). The Pacaya-Samiria Reserve was selected because it offered a relatively pristine environment in which to obtain baseline data. In this paper, I summarize unpublished and published results of an investigation of the distribution, relative abundance, group size, reproductive seasonality and conservation status of tucuxi in Peru's Pacaya-Samiria National Reserve. More detailed presentation of methods, results, and

discussion can be found in McGuire (2002), McGuire and Aliaga-Rossel (2007), and McGuire and Henningsen (2007).

Material and Methods

The Pacaya-Samiria Reserve is located in the far western Amazon Basin (Figure 1), and at 208000ha, it is the largest reserve in Peru, with over 10000km of linear waterways. Four seasons, each approximately three months long, are determined by water levels: high water, falling water, low water, and rising water. Twenty-eight research cruises were conducted between 1996-2000 (312d), and all seasons and aquatic habitat types were surveyed (Figure 1, Table 1).

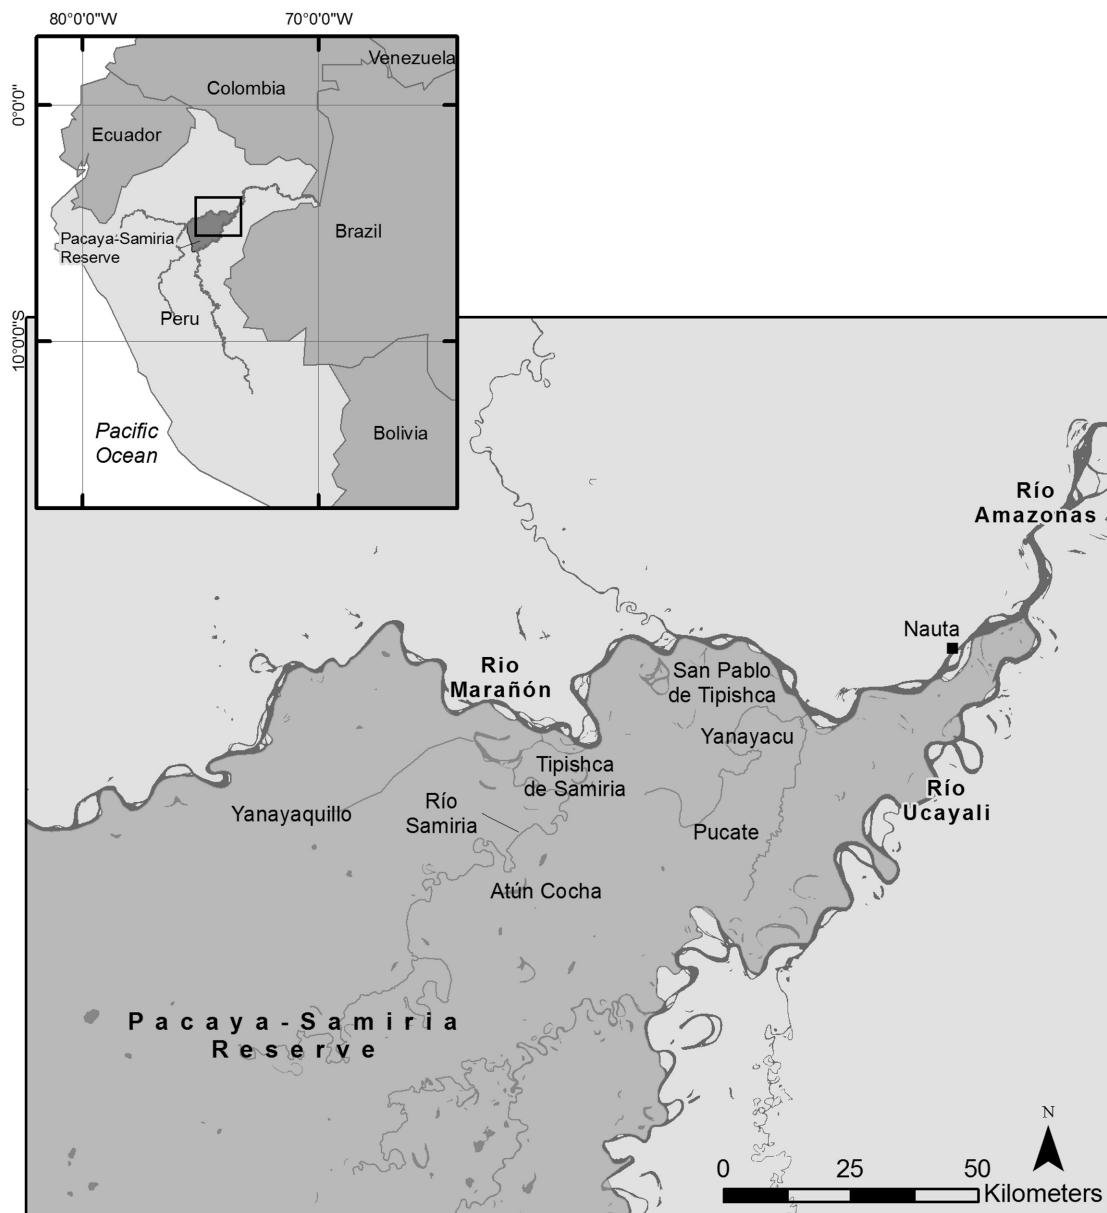

Figure 1. Map of the study area in the Pacaya-Samiria National Reserve, Peru.

Table 1. Rivers surveyed for tucuxis in the Pacaya-Samiria Reserve, Peru.

LOCATION	MEAN WIDTH (m) DURING HIGH WATER	LENGTH OR AREA SURVEYED	WATER TYPE ¹
Marañón River	910	82.0km	white
Samiria River, section 1*	300	16.0km	mixed white and black
Samiria River, section 2*	152	163.0km	black
Yanayaquillo River	49	5.5km	black
Atun Caño	50	5.0km	black
Yanayacu River	99	10.7km	black, mixed in lower reach
Pucate River	104	5.8km	black
Lake San Pablode Tipishca	450	15.0km ²	mixed
Lake Atun Cocha	645	6.0km ²	black
Lake Tipishca del Samiria	878	14.6km ²	black

*Because of differences in water type, width, boat traffic, and bank vegetation, the Samiria River was divided into two sections for surveys: section 1 was the 16km reach from the mouth to the ranger station controlling access to the Reserve, and section 2 was upriver.

¹Black waters are relatively transparent and high in tannic acids derived from local forest vegetation, while white waters are rich in nutrients and sediments from Andean runoff.

Data collection consisted of boat-based surveys of dolphins and habitat, photographs and necropsies of dolphins, and interviews with local people. Surveys were conducted from a 20m long riverboat with 1m draw and an observer eye height of 7m (1996-1999) and an 18m long riverboat with a 0.9m draw and an observer eye height of 3.5m (2000), traveling at a mean speed of 9km/h. Two experienced observers and two to four assistants scanned a total arc of 225° extending from mid-bow towards stern on each side. Time of day, location (using GPS), distance to nearest shore, number and species of dolphins, and presence of neonates were recorded for each sighting. Tucuxi were differentiated from sympatric '*'bufeo'* or '*'boto'* (*Inia*) on the basis of dorsal fins, body size and shape, and surfacing behavior. Groups were defined as dolphins of the same species within five body lengths of each other. Every 10min, the survey vessel position, wind speed, boat speed, river depth, and river width were recorded. Most waterways were surveyed with direct counts and 100% strip-width transects. The Marañón River was surveyed with a modified strip transect because of navigational hazards and strong currents; here the survey vessel traveled within 50-100m of the erosional shore, and traversed the river when this shore changed sides as the river turned, resulting in a strip transect of 50-100m on one side, and indefinite width on the other. Smaller tributaries were sampled from skiffs powered by outboard motors. Behavioral observations and photographs for photo-identification were collected opportunistically during transects of lakes and rivers, and were made primarily during days spent scanning confluences areas from stationary vessels, sunup to sundown, for a total of 461hr.

Data were stratified according to season, time of day, habitat and location. Single-factor ANOVAs were used to compare means among similar strata, such as encounter rates according to season. Data were first examined for normality. When necessary, data were transformed with the function $\ln(x+1)$ in order to correct for unequal variance. If the transformation failed to improve normality, the Kruskal-Wallis test was used to compare sample medians. Results of statistical tests were considered significant at the $P \leq 0.05$ level. Standard deviations (SD) about the mean are in parenthesis following the mean. Coefficients of Variance (CV), defined as the standard deviation of a sample divided by the mean of the sample, are reported as a measure of the relative variability of estimates.

Results

Tucuxi encounter rates were highest in confluences, intermediate in lakes, and lowest in rivers (Tables 2 and 3). Encounter rates generally increased with river width, and with lake size. In the Marañón River, 53% of tucuxis were seen <100m from shore, 24.5% 100-200m, and 22.5% >200m, and 68% of large groups (> five tucuxis) were seen in confluences or around mid-channel islands. In the Samiria River, 35% of large groups were seen in confluences, and 41% were seen in river bends < 90%. Tucuxis occurred throughout all of the surveyed lakes, but were encountered in highest concentrations in the deepest areas of the lakes. Tucuxi occurred in lakes as shallow as 1.8m mean depth and in rivers as shallow as 3.0m mean depth (Table 4). Encounter rates did not differ significantly according to season (Tables 2 and 3) in

any of the surveyed lakes or rivers (except when tucuxi were absent during extreme low water in the shallowest waterways), and variation in dolphin abundance was greater within-seasons than among-seasons. In confluences, tucuxi densities were inversely related to seasonal water levels. There was no association between tucuxi occurrence and time of day in any habitat ($P = 0.14$; sampling restricted to 0600-1800hr). Tucuxi were most often seen as singles or pairs: 37% of all sightings were of single dolphins, 38% were of pairs, 14% of triples, and 10% were of groups of greater than three and up to 13 individuals. Seasonal differences in mean group size were not statistically significant in most locations, and mean group size was always between one and three (Table 5). Neonates were observed in all seasons, with a slight peak during high water. Mating behavior was only observed once during falling water and once

during rising water. Photo-identification was unsuccessful; tucuxis were difficult to identify because they avoided boats, did not remain long in any one area, surfaced quickly and unpredictably and generally lacked visible, distinctive marks (McGuire and Henningsen, 2007). Different researchers working in the Pacaya-Samiria Reserve over a 10yr period have used different survey methods and have obtained different dolphin encounter rates for the same locations (Table 6). Direct counts of dolphins made in the same lake on the same or consecutive days also differed between different survey methods (using different routes, vessels, and number of observers; Table 7). One dead tucuxi was encountered between 1996-2000: an adult female, 176cm total length (straight length, snout to tail notch), found dead and entangled in a net used for illegal capture of aquatic turtles.

Discussion

Confluences were areas of greatest tucuxi densities, which is not surprising given that confluences are known to provide year-round availability of deep water and high densities of fish (Lowe-McConnell, 1975; 1979). Tucuxi encounter rates were higher in lakes than rivers, and in wider rivers rather than narrow channels, which is consistent with diet studies (da Silva, 1983) indicating that tucuxi primarily consume schooling fish found in open waters. It would be interesting to know if a longitudinal density gradient for tucuxis exists along the Amazon River, with densities increasing as the river widens toward the delta. Encounter rates from tucuxis in the study were within the range of encounter rates reported elsewhere in the Amazon (Borobia *et al.*, 1991), although it is difficult to compare densities obtained with the variety of methods used in different study areas. Absolute water depth, rather than relative seasonal changes in depth, appeared to have been most strongly associated with tucuxi distribution. Rather than exhibiting a predicted gradual change in distribution which closely tracked water levels, tucuxis remained in lakes and smaller rivers until a minimum depth threshold was reached, at which point they moved to confluence areas. Distinct seasonal changes in group size might have suggested the onset of a mating and/or calving season, but insubstantial (<1) changes in mean group size and observations of aseasonal calving and mating behavior indicate that reproduction occurs year-round in the Peruvian study area.

Photo-identification was unsuccessful as tucuxis were difficult to identify because they avoided boats, did not remain long in any one area, and surfaced quickly and unpredictably. Trujillo (1994), Henningsen (1998), and Zúñiga (1999) had some success with photo-ID of tucuxi, although they did not find the technique robust enough to study social structure or estimate population size. Future

photo-identification results may improve with focal follows and digital video camera with screen capture.

Differences in survey methods, such as observer eye height, transect type, number of observers, vessel speed, use of correction factors, and frequency of survey all affected population estimates. Considering the high degree of intra-seasonal and daily variability (differences within a location as great as 51 and 17 dolphins, respectively) of tucuxi counts made by the same researcher using the same method in the same locations, it should be emphasized that future population assessment should sample frequently within seasons as well as between, use standardized methodology, and be aware that 'rapid assessment transect' type surveys may yield misleading results.

Local people in the Reserve did not seem to have the same myths and general apprehension about tucuxis as for the other sympatric dolphin, *Inia*. There was no evidence that tucuxi were poisoned by fishermen, unlike *Inia* (Reeves *et al.*, 1999). It is remarkable that only one dead tucuxi was encountered during the study, while 12 dead *Inia* were encountered during this time, and live tucuxi and *Inia* were encountered in approximately equal numbers (McGuire, 2002). The apparent lower rate of anthropogenic mortality of tucuxis compared to botos may be due to differences in local attitudes towards the two species. Potential threats to tucuxi in this region were entanglement in fishing gear, over fishing of prey fish by humans, mercury in migratory fish from gold mining elsewhere, oil spills, ship strikes, water pollution, and disturbance from boats. Tucuxi teeth were found in local markets; although cause of death could not be determined, vendors reported the dolphins had been killed incidentally in fishing nets. As of 2000, tucuxi populations in the Pacaya-Samiria Reserve appeared to be relatively healthy, and studies indicate that population estimates in the Samiria River system were stable over the period 1991-2000 (Leatherwood, 1996; Henningsen, 1998; Zúñiga, 1999; McGuire, 2002).

Acknowledgements

The following people and institutions are thanked: The administration and field workers of the Pacaya-Samiria National Reserve, the crews of the *Delfin* and *Miron Lento*, Marc Bourdon, the DeMatteos, Earthwatch Institute, Francisco Estremadoyro, Familias Aliaga, Pinedo and Tenazoa, INRENA, Dave Jepsen, Thomas Henningsen, the Kramarae/Kramer family, LGL Alaska Research, Steve Leatherwood, the McGuires, Víctor Morales, Oceanic Society Expeditions, Gustavo Pereyra-Panduro, Dulcie Powell, Pronaturaleza, Randy Reeves, the Texas Institute of Oceanography, Gerónimo Vega Quevare, the Virtual Explorers, Kirk Winemiller, Bernd Würsig, Elizabeth Zúñiga, and the volunteers of Earthwatch, Elderhostel, and the Oceanic Society. Thanks to Enzo Aliaga-Rossel, Barb Lagerquist, Lucy Moore, and Paulo Flores for their helpful reviews. This research was conducted under permits #53-97, #27-99, #02-S/C 2000-INRENA-DGANPFS-DANP.
